

Slowly Changing Dimension (SCD) Type 1

Explanation

This method overwrites old with new data, and therefore does not track historical data. If customer relocates, the customer_address record will be overwritten.

Pros: It's easy to maintain.

Cons: there is no history of customer_address changes.

Slowly Changing Dimension (SCD) Type 2

Explanation

This method tracks historical data by creating multiple records for a given natural key in the dimensional tables with separate surrogate keys and/or different versions numbers.

For every customer relocation a new record is inserted. Each inserted record has effective_date and current_flag, identifying which customer address will be in effect from which date, and which address is the current customer address.

Pros: Unlimited history is preserved with each insert. Every customer_address record has an effective_date and current_flag, marking customer_address duration and it's current status.

Cons: Transactions that reference a particular surrogate key (customer_address_id) are then permanently bound to the time slices defined by that row of the slowly changing dimension table.
